TARGETED EXPERTISE / BACKEND RELIABILITY AND DATA ISOLATION

Secure the tenant boundary. Prove the recovery path.

ARAZVERA TECHNOLOGIES | Advanced Backend Engineering Profile

GitHub proof portfolio | contact.arazvera@gmail.com

PROBLEMS WE TARGET

SaaS access-control hardening Cross-tenant exposure, missing server-side permission checks, unsafe SQL policy boundaries and regression tests.

Failed background work & webhooks Duplicate or out-of-order events, uncertain outcomes, retries, dead-letter review and replay-safe processing.

Database integrity & recovery Optimistic version conflicts, partial updates, isolated backups, restore rehearsals and actionable release blockers.

VERIFIABLE ENGINEERING EVIDENCE

09	75	14
Public synthetic cases	Public automated tests	DB-level RLS tests

Public tests are independent of the separate private Level 2 baseline (25 kit families; 313 local tests). All are synthetic evidence, not customer production installations.

SELECTED ENGINEERING CASE STUDIES

09 / PostgreSQL RLS & restore 14 tests + restored-policy verification

Actual PostgreSQL 16 policy enforcement, independent tenant database roles, permission denial, transaction tests and a same-server restore drill.

Inspect source and test matrix

08 / Authorized FastAPI + PostgreSQL 14 API + PostgreSQL integration tests

RS256 JWT rejection paths, scoped API endpoints, active DB membership and idempotent optimistic writes.

Inspect source and test matrix

06 / Webhook failure recovery 16 tests

HMAC-signed HTTP intake, SQLite durable job leasing, retry, manual reconciliation and restart persistence.

Inspect source and test matrix

07 / Data reconciliation 21 tests

Validated CSV/SQLite imports, dry run, rollback, quarantined records and optimistic conflict handling.

Inspect source and test matrix

CLIENT-FOCUSED TECHNICAL DELIVERABLES

Scoped work. Reproducible results.

01 / Authorization boundary review

Reproduce a reported isolation or permission defect in authorized staging; inspect role policies, scopes and SQL privileges; deliver negative-path tests and a severity-ranked finding report.

Acceptance evidence: failing test reproduced, proposed fix, passing regression, limitations documented.

02 / Backend reliability repair

Trace webhook duplication, lost jobs, stale writes or partial retries; implement one bounded recovery improvement using transactions, idempotency and operator review gates.

Acceptance evidence: incident reproducer, persistent state checks, rollback/retry tests and readable handover.

03 / Database safety and restore rehearsal

Review schema/backup assumptions and run a controlled restore in an isolated clone; compare data, roles, policies and reproducibility.

Acceptance evidence: backup manifest, verified restore report, release blockers and untested scenarios.

WORKING STACK & QUALITY PRACTICE

Python 3.11/3.12 | FastAPI | PostgreSQL 16 | psycopg | RLS & SQL privileges | JWT / RS256 | JSONB | SQLite | HMAC-signed webhooks | GitHub Actions | Docker | negative-path tests | isolated restore drills.

HOW WE STRUCTURE THE HANDOVER

Written acceptance scope; a reproducible failing case; minimal reviewed changes; automated tests and evidence logs; security exclusions; restore/rollback notes; client-owned credentials and final acceptance.

EVIDENCE AND DEPLOYMENT BOUNDARIES

No assertion of an external enterprise deployment, audited SOC 2 controls, independent penetration-test certification, production Supabase experience, a shipped payment ledger, 24/7 SLA or multi-region disaster recovery. The PostgreSQL restore proof uses two databases in one disposable local container; cluster roles require separate provision on a new server.

APPLY TO THE RIGHT PROJECTS

Best fit: bounded SaaS release blockers, authorized tenant-access reviews, recoverable API/webhook workflows and staged database-integrity reviews. Larger production-security or cloud architecture engagements require additional client-specific validation and qualified oversight.
